

# Introduction to Git

---

GEO2020 - 15/12/2017

Stelios Vitalis

## 1. Version Control

1.1 Why do we need it?

1.2 What is it?

1.3 Architecture

1.4 Commits

1.5 Branches

## 2. Git

2.1 Definitions

2.2 Init or Clone

2.3 Add and Commit

2.4 Checkout

2.5 Merge

2.6 Pull

2.7 Push

## 3. Github and Workflow

# Versioning and Collaboration

*The general concept*

It's useful because:

- It tracks history of our work
- It allows us to work as a team
- It can be used to extract statistics about a project

## Is it really new?

*Cloud already uses it*

You have probably used it on documents if you use:

- Dropbox + MS Office
- Google Drive + Google Docs
- OneDrive + MS Office

# Version Control System (VCS)

## Definition

### Definition

*Version Control is the **management** of changes to documents, computer programs, large web sites, and other collections of information.<sup>1</sup>*

---

<sup>1</sup>Wikipedia

# Version Control System (VCS)

## *Benefits*

A VCS:

- keeps **revisions**
- allows for **true collaboration**
- encapsulates **workflow** (e.g. track time, issues, project management)

## VCS vs Cloud

*Although not really a comparison*

	VCS	Cloud
Revisions	Manual	Auto
<b>Revision Information</b>		
Author	✓	✓
Timestamp	✓	✓
Message	✓	✗
<b>Collaboration</b>		
Sharing	✓	✓
Concurrent working	✓	?
Branching	✓	✗

But don't be confused... It can't replace your cloud file storage!

# VCS

## *Definitions*

### Repository

A storage location where all versions and information about them are stored.

### Workspace

The actual working directory of the user.

## Types of VCS

There are two types:

- Centralised
  - Subversion (SVN)
  - Microsoft Team Foundation Server (TFS)
  - Concurrent Versions System (CVS)
- Distributed
  - Git
  - Mercurial

# Centralised

## Architecture

A server is the only repository and every user has a workspace.

# Distributed

## Architecture

No “master” server. Every user has a repository and a workspace.

## Repository “internals”

*It's a graph*

This nodes are called **commits** or **revisions**.

# Commit or Revision

## *Information*

Every commit has:

- **ID:** some sort of identifier
- **Author:** name and email of user who commits
- **Timestamp:** time of commit
- **Message:** what the commit contains

and, of course, the **changes** of the files that are submitted.

# Repository “internals”

## *Branching*

## Merging

## 1. Version Control

1.1 Why do we need it?

1.2 What is it?

1.3 Architecture

1.4 Commits

1.5 Branches

## 2. Git

2.1 Definitions

2.2 Init or Clone

2.3 Add and Commit

2.4 Checkout

2.5 Merge

2.6 Pull

2.7 Push

## 3. Github and Workflow

# Git

## *Some History*

Git was created by Linus Torvalds in 2005 because there was no decent version control system to maintain the Linux kernel. He described the tool as "the stupid content tracker".

# Git

## *Some History*

He setup the following objectives:

- Performance
- Take CVS as an example of what not to do; if in doubt, make the exact opposite decision
- Support a distributed, BitKeeper-like workflow
- Include very strong safeguards against corruption, either accidental or malicious

# Git

## *Definitions*

- Every commit has an ID which is its hash. E.g.:  
2c7ae1b9865e58797ba326d2f7a115bebb034fd7
- We call the “current” commit as HEAD.

# Git

## Definitions

## Create a repository

*From scratch*

```
git init
```

Creates a new empty repository.

The *working directory* is not affected, but an empty repository and index is created.

## Create a repository

*From a remote*

```
git clone remote_address
```

Creates a copy of an existing online repository.

- A new folder is created.
- All commits/branches etc. are copied locally.
- The source repository is set as the *origin* remote.

## Status

*See where you stand*

```
git status
```

Gives all information about the current state of repository and index.

- Shows current branch and difference with remote.
- Shows the staged files.
- Shows changed but not staged files.
- Shows untracked files.

## Create a commit

*Add files to the index*

```
git add filename
```

Adds the file to the index. We say it's **staged**.

- The current file from *working directory* is copied to the *index* only if it has changes compared to HEAD.
- The *filename* can be a pattern. Eg. "git add ." will add all files.
- Nothing has been committed yet.

git add file.txt

(a) Before...

(b) ... and after

## Create a commit

*Commit staged files*

```
git commit -m "message"
```

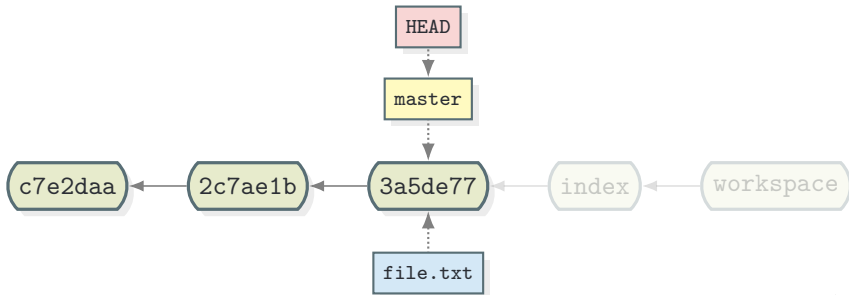

Creates a commit from a copy of the index.

- The new commit has the given message.
- After the commit, the index is cleared.
- The *HEAD* and the current *branch* tags are moved to the new commit.

`git commit -m "Changes to file.txt"`

(a) Before...

(b) ... and after

## Move to a commit

*Change branch or version*

```
git checkout ref
```

Moves to a branch/commit and changes the working directory accordingly.

- The *ref* can be a branch name, commit id or something else...
- The *HEAD* moves to the referred commit.
- The current branch changes (if a branch name is given).

git checkout 2c7ae1b

(a) Before...

(b) ... and after
